

Introduction to Functions:- Computing

define new functions:-

we define functions using the `def` command

meta data

Information
(a baray ma
Information)

```
def square(x):  
    return x * x
```

→ input that the function take 1 variable
so 1^{or} 2 than
→ all things called body
this space is indent (4 spaces recommended) press tab

~~press~~ (parameter or formal parameter)
square(5) → call

out 25 → actual parameter, argument

Comment in python:-

by # starting

Obviously we call a function within other function:-

```
def sum_squares(x, y):  
    return square(x) + square(y)
```

```
result = sum_squares(3, 4) > arguments  
result  
25
```

Default value:-

We can give meaningful default values to arguments. Let's see an example from our square-root function.

```
def sqrt(num, guess=1):  
    print("Finding square root of ", num, "starting  
    with guess: ", guess)
```

agar kisi na guess ki value na dekhji to ham 1 istaalkreing.

`sqrt(36, 0.0)`

Finding square root of 36 starting with guess 0.0

`def sqrt(num, guess=1)`

↳ function parameter default value
